(54) Hard organopolysiloxane release coating.

(57) What is disclosed are organopolysiloxane release coatings which are curable on a substrate and which consist of a base siloxane copolymer containing $\text{CH}_3\text{SiO}_{3/2}$ units; $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5(\text{CH}_3)\text{SiO}$ units and $(\text{C}_6\text{H}_5)_2\text{SiO}$ units; $\text{CH}_3\text{SiO}_{3/2}$; a fluid polysiloxane, and a curing agent. They are especially useful on commercial and household cookware and bakeware.

HARD ORGANOPOLYSILOXANE RELEASE COATING

This invention deals with hard, curable, clear and pigmented release coatings for cookware and bakeware. For years, it was common in the commercial baking art to utilize natural fats, greases and vegetable oils for 5 coating cookware to obtain release of the cooked goods from the cookware, but beginning with 1960, the commercial cooking industry, especially the baking industry, was introduced to polyorganosiloxanes as a means of obtaining release of foods and baked goods from the cookware.

10 The release coating technology moved quickly as various curable, thus more durable, organopolysiloxanes were introduced to the industry. These more advanced release coatings usually consisted of hydroxy-containing fluids, which were usually linear polydimethylsiloxanes, 15 dissolved in higher viscosity phenylmethylpolysiloxanes or, such linear materials were combined with solvent-based or solventless organopolysiloxane resins and cured onto certain substrates, by the application of heat, to cause condensation reactions. Other, more modern, release 20 coatings utilizing siloxanes involved the combination of a linear, hydroxylated, diorganopolysiloxane, a phenylmethyl-polysiloxane and an organopolysiloxane block copolymer which is heat cured onto the substrate. Such a coating is described in U.S. Patent No. 3,308,079, issued March 7, 25 1967 and cures through condensation reactions of the silanols present in the siloxane components.

A similar release coating material is described in U.S. Patent No. 3,308,080, issued March 7, 1967, except that the phenylmethylpolysiloxane does not form part of the composition.

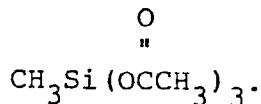

In U.S. Patent No. 3,925,276, issued on December 9, 1975, there is described a process for preparing a silanol-containing organopolysiloxane resin which is useful as a release resin. This type of resin is described as giving good release to sugar-containing baked goods. This type of resin, with a fairly specific ratio of alkyl and aryl siloxanes, cures by heat curing through condensation reactions.

U.S. Patent No. 4,204,021 deals with a composite layer concept for release purposes wherein a first coating is applied to a porous ceramic layer and impregnates the porous ceramic layer. The top layer is a release layer and the patent describes organopolysiloxanes as part of a group of known release coatings wherein there is present in the organopolysiloxane, an unsaturated radical on silicon, which when combined with a photosensitizer, can be cured by a free radical light source.

British Patent 1,448,985, issued September 8, 1976, describes pigmented release coatings that are obtained by a two coat composite method, in which, the bottom coat is a cured pigmented coating and the top coat is a hard, transparent release coating. The hard, transparent release coating is generally described as a silicone resin that gives release. No additional information is given about the release coating which would enable one to ascertain its composition or cure mechanisms.

Finally, there is disclosed in U.S. Patent No. 3,419,514, issued December 31, 1968, an "air-dried" version of an organopolysiloxane-based release coating. The coating contains a phenylmethylpolysiloxane having a hydroxyl content of at least 3 percent by weight, a phenyl to silicon ratio of at least 0.3 and a total phenyl and methyl to silicon ratio of from 1.2 to 1.7; $RO(R'CH_2O)_2H$;

methylpolysiloxane fluid having at least 2% by weight of silicon-bonded hydroxyl groups and

5 These materials cure at room temperature in a very short period of time by reaction of the acetoxy silane with moisture in the air and subsequent condensation reactions under the influence of catalysts.

Since the instant invention can be described
10 in-part as an "air-dried" release coating, the '514 reference is, in the applicants' opinion, the closest prior art. None of the other references are considered by the applicants to anticipate or to obviate the instant invention. Furthermore, even though the '514 patent is
15 considered pertinent prior art, it differs from the instant invention in at least the following manner: the crosslinking means of the instant invention consists of the inclusion of $\text{CH}_3\overset{\text{O}}{\underset{\text{"}}{\text{Si}}}(\text{OCH}_3)_3$ in the composition. This alkoxy silane, upon hydrolysis, liberates non-corrosive methanol
20 which is removed quickly during the cure reaction whereas the crosslinking means of the '514 reference liberates acetic acid during the cure reaction. This acetic acid is both corrosive to metal substrates and is extremely difficult to remove during the cure reaction.

25 Also, the essential base siloxane of the '514 reference is a phenylmethylpolysiloxane whereas the essential base siloxane of the instant invention is a copolymer of four specific alkyl and/or aryl-containing siloxane units. Component (c) of the reference material is
30 similar in composition to component (C) of the instant invention but the instant composition does not contain the organic polyether, component (b) of the '514 reference. Therefore, even though the two inventions have a common

ingredient, i.e., component (c) in each case, and even though they both claim to have air-dry properties, it is quite obvious that the comparison stops there and the material of the instant invention is not the same as the 5 material of the '514 reference.

This invention deals with a composition of matter comprising (A) 100 parts by weight of a hydroxyfunctional polysiloxane resin copolymer containing $\text{CH}_3\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units, $(\text{C}_6\text{H}_5)_2\text{SiO}$ units and $\text{C}_6\text{H}_5(\text{CH}_3)\text{SiO}$ units 10 wherein there is present 0.5 to 5 weight percent hydroxy radicals attached to silicon atoms, the organic group to silicon ratio is from 0.8 to 1.4 and the C_6H_5 - to silicon ratio is from 0.35 to 0.85; (B) from 4 to 240 parts by weight, based on 100 parts of (A), of $\text{CH}_3\text{SiO}_{3/2}$; (C) from 15 0.2 to 6 parts by weight, based on 100 parts of (A), of a fluid polysiloxane having the formula $(\text{RR}'\text{R}''\text{Si})_2\text{O}[(\text{CH}_3)_2\text{SiO}]_x$, wherein x has a value of from 250 to 850, R is OH or CH_3^- and R' and R'' are CH_3^- , wherein there is present in component (C), less than fifteen 20 percent by weight of $(\text{CH}_3)_3\text{SiO}$ units; and (D) from 0.48 to 6 parts by weight, based on 100 parts of (A), of a curing agent.

The first component of this invention, component (A), the base siloxane is a hydroxy-functional polysiloxane 25 resin copolymer containing $\text{CH}_3\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5(\text{CH}_3)\text{SiO}$ units and $(\text{C}_6\text{H}_5)_2\text{SiO}$ units. It should be noted that this base siloxane contains no $(\text{CH}_3)_2\text{SiO}$ units and further, this base siloxane must have from about 30 0.5 to 5 weight percent of hydroxy radicals which are attached to silicon atoms. Further, this base siloxane resin has an organic group to silicon ratio of from 0.8 to 1.4 and a C_6H_5 - to silicon ratio of from 0.35 to 0.85.

This copolymer can be prepared by known commercial means such as, for example, by the hydrolysis and condensation of chloro- or alkoxy silanes. These base siloxanes are commercially available and elaboration on the 5 details of their preparation is believed to be unnecessary herein. It should be noted that upon condensation of the hydrolyzate, and subsequent catalytic bodying techniques known in the art, this base siloxane can be obtained essentially solvent-free and it is preferred for this 10 invention that the base siloxane be utilized to form the composition of this invention in such a form. This allows the solids content of the final composition to be varied such that handling properties, economy in shipping the formulations and, the thickness of coatings on the 15 substrates can be widely varied. If it is required that the base siloxane be used in solvent, the base siloxane can be easily dissolved in common organic solvents such as xylene, toluene, naphtha and the like. This component is generally used at 100 parts by weight in the composition.

20 Component (B) of this invention, $\text{CH}_3\text{SiO}_{3/2}$, is a residual product derived from the alkoxy silane, $\text{CH}_3\text{Si}(\text{OCH}_3)_3$. The alkoxy silane is added to the formula neat, as it is a low viscosity fluid material which helps solubilize some of the higher molecular weight components 25 and helps the total composition to become homogeneous upon initial mixing. It is believed that the alkoxy silane, under the influence of the curing agent, component (D) (to be described infra), initially reacts with the hydroxyl groups of the base siloxane and the hydroxyl groups of the slip agent, component (C) (to be described infra), to form 30 low molecular weight alkoxy-functional siloxanes which eventually react further to liberate methanol and form silanol groups which eventually condense to form high

molecular weight materials and crosslinking sites which cure the composition. Component (B) is a common product of commerce and is readily available and therefore, no additional details on preparation are required herein. For 5 purposes of this invention, there is generally used from 4 to 240 parts by weight of component (B), for every 100 parts of component (A). It is preferred, however to use from 50 to 150 parts by weight of component (B) and it is most preferred to use 80 to 120 parts of component (B).

10 Component (C) of this invention, the fluid polysiloxane, has the general formula

wherein x has a value of from 250 to 850, R is an OH or CH₃- radical and R' and R'' are CH₃- radicals, wherein there 15 is present in component (C), less than fifteen percent by weight of (CH₃)₃SiO units.

This component is the "slip" component of the composition, that is, this component is the ingredient in the formulation that is primarily responsible for the 20 release characteristics of the cured coating. Component (C) is readily manufactured by well-known means by those skilled in the art and elaboration on such means is deemed unnecessary herein.

For purposes of this invention, the fluid 25 polysiloxanes (fluid siloxanes) useful in this invention are those having hydroxy endblocking, for example

combined with those siloxanes having partial substitution 30 of the hydroxyl groups with (CH₃)₃SiO units. Because of the nature of the method used to prepare such materials, it is also within the scope of this invention to include small amounts of fully endblocked polysiloxanes, for example,

For purposes of this invention, "small amounts" means less than about 10 weight percent, based on the total weight of component (C) in the inventive composition. The value of x serves to indicate the approximate viscosity of the fluid siloxanes. Thus, preferred for this invention are fluid siloxanes having a viscosity of from 8,000 to 20,000 cps. 5 Most preferred for this invention are fluid siloxanes having a viscosity of from 11,000 to 14,000 cps.

Component (C) is used in this invention at 0.2 to 6 parts by weight, based on 100 parts of component (A). 10 Most preferred is the use of the component (C) at 0.5 to 2 parts per 100 parts of component (A). The component (C) is generally utilized at 10 weight percent solids in a solvent such as toluene.

The fourth component of this invention, component (D), the curing agent, is a silanol condensation catalyst. Preferred for this invention are titanate catalysts as they tend to promote the efficient reaction of the alkoxy-silanes with the silanols of components (A) and (C) and, the titanates also tend to promote the condensation 20 reaction between the silanols. Especially preferred are the titanate esters, tetraisopropyltitanate and tetrabutyltitanate. These catalysts are used neat, that is, they are generally used without solvent since they appear to be highly compatible with the components (A), (B) 25 and (C).

Component (D) is generally used in this invention, in the amount of 0.48 to 6 parts by weight, based on 100 parts of component (A). Most preferred for this invention is 1 to 3 parts of component (D). The 30 titanate curing agents are commercially available.

Optionally, solvents can be used with the inventive composition or the composition can be used at

100% solids. It is preferred that the compositions be used in a solvent solution for ease of handling, flow out properties and film thickness control. Generally, the compositions are present in the solvent at about 20 to 70
5 weight percent non-volatile materials. Preferred for this invention are the common organic solvents. Especially preferred are xylene, toluene, isobutylisobutyrate, naphtha and the like. Most especially preferred are toluene solutions containing about 40 weight percent non-volatiles.

10 The method of preparation of the inventive compositions is not critical. The four components (A),
- (B), (C) and (D) are mixed together and homogenized by stirring or shaking. When first mixed, the mixture is opaque to translucent in appearance but within a few
15 minutes, the mixture starts to clear and within a short time, for example, 2 hours, the mixture is quite clear. It is ready for use as a coating at that time or the mixture can be stored at room temperature for several months.
20 Sometimes, the first three components are thoroughly mixed until transparent and the curing agent, component (D), is added just before use. This method allows for enhanced shelf stability of the three component composition. The solvent, if used, can be added at any point in the preparation. If solvent is to be used, it is preferably
25 added at the beginning of the preparation in order to facilitate the preparation.

Components (A) through (D) are the essential ingredients of this invention but it is contemplated herein that aside from the use of solvents, there can also be included such optional ingredients such as pigments, metal flakes and powders, stabilizers, colorants, flow and film forming agents and the like.

In use, the coating can be applied by any conventional coating technique such as spraying, dipping, brushing or by the use of a doctor blade. For this invention, spraying and dipping are preferred. Most 5 preferred is a dipping technique, as spray coating tends to lead to somewhat softer cured coatings.

The compositions of this invention can be applied to most surfaces without the use of a primer. For some applications, however, it may be desirable to use a primer. 10 These coatings can be applied to most solid substrates but it is preferred for purposes of this invention, to coat metal substrates, especially metal bakeware and cookware such as steel, copper, aluminum, tin, magnesium and alloys of such metals. As far as is known by the inventors, these 15 coatings can be used for almost any type of food such as baked goods, fried and broiled meats, vegetables, sauces and gravies.

These compositions, when in the fluid form, are characterized by ease of preparations, shelf stability, 20 handling characteristics and both room temperature and elevated heat curability. When coated and cured on a substrate, these cured coatings impart highly desirable release characteristics, they are hard coatings, they adhere to the substrate without the use of primers and they 25 exhibit hot oil and hot and warm soap resistance so that clean-up of the coated articles is minimal.

These materials are useful in the home but they find greater use in commercial cooking and baking applications.

30 Now, so that those skilled in the art more clearly understand the invention, the following examples are presented and these examples should not be construed as

narrowly limiting the invention as set forth in the claims and the specification.

For purposes of these examples, the following applies.

5 The metal panels used in these tests were purchased from the Q-Panel Company, Cleveland, Ohio, U.S.A.

Room temperature cures were at ambient conditions of 25°C.

10 The slip material used in these formulations is a 10 weight percent solvent solution of a hydroxy endblocked polydimethylsiloxane of approximately 12,000 cps which contains less than 15 percent by weight of trimethylsiloxy endblocking.

15 Special Naphtholite is a solvent manufactured by Chemical Central, Chicago, Illinois, U.S.A.

The following test procedures were used to evaluate the resin coatings.

(a) Pencil Hardness:

20 A pencil lead of known hardness (4B-softest to 9H-hardest) is sanded flat on the end. The end is then held at a 45° angle on the coating and pressed into the coating. Pencils of increasing hardness are used until the resin film is gouged. The pencil hardness recorded is that pencil number just prior to the one which breaks through the film. >9H means the hardest pencil did not break through the coating. (4B, 3B, 2B, B, H, 2H, 3H, 4H, 5H, 6H, 7H, 8H, 9H).

(b) Slip Angle:

30 A weight which is a cylindrical weight of approximately 3 oz. is wrapped with 8 layers of cheesecloth and placed atop a panel that has been coated with the resin and cured. The panel is

then inclined until the weight begins to slide. The angle of initial slipping is the slip angle. This indicates the release properties of the cured resin film.

5 (c)

Steam Stability:

The coated panels are placed over a glass beaker of boiling deionized water for 15 minutes. Any whitening or adhesion loss is noted as failure.

(d)

10

Wetting is a visual observation of the film for defects such as cratering or rivulets of resin.

(e)

15

Salt Spray:

The coated panels are placed in a salt fog chamber for 100 hours, then observed for corrosion of the metal or adhesion loss of the resin.

(f)

20

MiBK Rub Test:

This test is used to test the degree of cure and integrity of the cured coating. The test is carried out by wrapping the peen end of a ballpeen hammer with 10 layers of cheesecloth and saturating the cheesecloth with methyl isobutyl ketone (MiBK). The hammer, with the cheesecloth contacting the coating, is rubbed across the coating, using only the weight of the hammerhead, until the resin coating is broken through to the bare metal. The number of back and forth rubs is recorded as the number of "double rubs" required to just break through the coating.

25 (g)

Crosshatch Adhesion:

This test is carried out by coating a metal substrate, curing the coating, and scratching through the coating with a sharp instrument to

form a grid of 10 squares on each side of the
grid. Scotch^R brand (3M Company, Minneapolis,
Minnesota, U.S.A) adhesive tape about 1" wide is
pressed sticky side down over the crosshatch with
normal pressure. The tape is then sharply
removed by pulling the tape away from the surface
in a direction parallel to the surface. The
number of small squares remaining on the surface
is reported as the % adhesion. An average of
these pulls is recorded. For purposes of this
invention, "good" means greater than 90% of the
squares remained after the tape pull.

Example 1

This sample was prepared by adding and mixing the
15 ingredients in a pint glass bottle on a revolving wheel
until the mixture was homogeneous. The mixture consisted
of 80 gms (100 parts by weight) of a hydroxyfunctional
polysiloxane resin having about five weight percent
hydroxyl groups on silicon and consisting of $\text{CH}_3\text{SiO}_{3/2}$
20 units, $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units, $(\text{C}_6\text{H}_5)_2\text{SiO}$ units and $\text{C}_6\text{H}_5(\text{CH}_3)\text{SiO}$
units and having an organic group to silicon ratio of
approximately 1.2 and a $\text{C}_6\text{H}_5/\text{Si}$ ratio of 0.6; 120 gms (150
parts by weight) of NS 66/3 Special Naphtholite (VM & P
naphtha of low aromatic content); 40 gms (50 parts by
25 weight) of Dowanol^R EB (ethylene glycol mono butylether),
manufactured by the Dow Chemical Company, Midland,
Michigan, U.S.A.; 40 gms (50 parts by weight) of dry
toluene and 1.64 gms (2.05 parts by weight) of a fluid
polysiloxane as described above.

30 Eighty gms of the above mixture (100 parts resin)
was treated with $\text{CH}_3\text{Si}(\text{OCH}_3)_3$ and tetraisopropyltitanate
(tipt) according to the formulations in Table I. When
cured, the properties shown on Table I were obtained.

There was used 0.24 gms of tipt (0.75 parts) for each sample and the substrate was R-39 cold rolled steel purchased from the Q-Panel Co.

Example 2

5 Several larger preparations of the compositions of Example 1 were prepared in essentially the same manner as in Example 1. Combined were 50 gms of the resin (100 parts), as described in Example 1, 88 gms (176 parts) of toluene, 56.6 gms (113.2 parts) of $\text{CH}_3\text{Si}(\text{OCH}_3)_3$, 1.6 gms
10 (3.2 parts) of the fluid polysiloxane as in Example 1 and 1.6 gms (3.2 parts) of tetraisopropyltitanate. These materials were revolved until homogeneous. This material was designated 2A. Sample 2B was the same except that 85 gms (170 parts) of $\text{CH}_3\text{Si}(\text{OCH}_3)_3$ and 1.9 gms (3.8 parts)
15 each of tipt and fluid siloxane were added and 2C was the same as 2A except that 113.3 gms (226.4 parts) of $\text{CH}_3\text{Si}(\text{OCH}_3)_3$ and 2.1 gms (4.2 parts) each of tipt and fluid siloxane were added. The formulations can be found on Table II. The substrate was R-39 cold rolled steel panels
20 purchased from the Q-Panel Company.

Example 3

This sample was prepared by adding and mixing the ingredients in a pint glass jar on a revolving wheel until the mixture was homogeneous. To the jar was added 160 gms
25 of a polysiloxane resin having about five weight percent hydroxyl groups and consisting of $\text{CH}_3\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units, $(\text{C}_6\text{H}_5)_2\text{SiO}$ units and $\text{C}_6\text{H}_5(\text{CH}_3)\text{SiO}$ units and having an organic group to silicon ratio of approximately 1.2 and a $\text{C}_6\text{H}_5/\text{Si}$ ratio of approximately 0.6;
30 50.6 gms of toluene; 96.8 gms of isobutylisobutyrate; 166.8 gms of Special Naphtholite 66/3 solvent; 6.4 gms of a slip material as described above and 325.9 gms of $\text{CH}_3\text{Si}(\text{OCH}_3)_3$. This mixture when cured will provide a $\text{CH}_3\text{SiO}_{3/2}$ to resin

ratio of 102/100. To this mixture was added 3.2 parts by weight of tetraisopropyl titanate as a curing agent. Into the mixture was then dipped two, 3" x 9" aluminized steel panels and when removed, they were allowed to air dry for 5 about 15 minutes. The coatings were then cured, one in an air circulating oven at 600°F for 6 minutes and the other at room temperature for two hours. The oven cured panel was designated 3A and had a pencil hardness greater than 9H and a methyl ethyl ketone (MEK) rub of 35 double strokes 10 while the room temperature cured coating designated 3B had a pencil hardness of greater than 9H and the MEK rub was 8 double strokes. The 3A coating passed the steam stability test.

Example 4

15 When the coating prepared in Example 3 above was cured 6 minutes @ 600°F without the addition of catalyst, the pencil hardness was greater than 9H but the coating failed to pass the steam stability test.

Example 5

20 When the coating prepared in Example 3 above was cured 6 minutes at 600°F using p-toluenesulfonic acid instead of tetraisopropyltitanate, at the same level, as a curing agent, the coating did not cure.

Example 6

25 Effect of the amount of catalyst

A mixture was prepared by adding to a pint jar 100 gms of the polysiloxane resin described in Example 1; 100 gms of $\text{CH}_3\text{Si}(\text{OCH}_3)_3$; 135 gms of the solvents described in Example 1 (at the same ratios); and 2.68 gms of slip material. The mixture was capped and revolved on the wheel until homogeneous and then aliquots of the mixture were taken and treated with varying amounts of tetraisopropyl-30 titanate catalyst according to Table III.

The mixtures were coated on aluminized steel panels and cured at 600°F for 6 minutes. The results are in Table IV.

5

	6A	> 9H	pass
10	6B	6H	pass
-	6C	7H	pass

Example 7The inventive coating as a release coating

A large batch of the inventive resin was prepared
15 (300 lbs.) in which the ratio of $\text{CH}_3\text{SiO}_{3/2}$ to resin was 1:1. Then the slip material was added to aliquots of the resin at 0.8 parts based on 100 parts of the resin and the catalyst was added to the aliquots after the aliquots were taken from the large batch and diluted to 40% solids in
20 solvent consisting of toluene, Special Naphtholite and isobutylisobutyrate at a weight ratio of 17.5: 49.5: 33. The resins, after catalysis were used to dip coat two separate aluminized 3" x 9" steel panels. After dipping, the coatings were allowed to air dry for about 15 minutes.
25 The coated panels were then cured at 600°F for 6 minutes. The formulations with catalysts and the results are shown in Table V.

These coatings had good crosshatch adhesion, hardness and excellent release.

30

Example 8

Two resin formulations were prepared by essentially the same method as Example 1. The formulations

and testing results are shown in Table VI. The substrate was R-39 cold rolled steel.

Example 9

Effect of cure temperature

5 A formulation was prepared in which there was present 100 parts of resin of Example 1 and 100 parts of $\text{CH}_3\text{SiO}_{3/2}$. Sixty gms of this resin was added to 90 gms of solvent as described in Example 7, 0.5 gms of 10 weight percent fluid siloxane and 2.0 gms of tetraisopropyl-
 10 titanate. The formulation was coated on R-39 cold rolled steel and cured at a given time and various temperatures as shown in Table VII.

10 Example 11

Several tin plated steel bakeware units were coated with the resin prepared in Example 3. The bakeware was tested in multiple tests such as pencil hardness, adhesion, hot oil resistance, dishwasher, release, hand dishwashing, cure and broiling resistance, all of which are standard tests. When cured for 6 minutes at 600°F, the following results (Table IX) were observed. In general, the coating was smooth and had good gloss.

15 Example 1220 A pigmented, hard curable coating of this invention

An inventive composition similar to that prepared in Example 2 was treated by mixing together 43 gms of toluene, 415 gms of a 50/50 weight blend of the base resin of Example 1 and $\text{CH}_3\text{Si}(\text{OCH}_3)_3$; 45 gms of silica (Syloid 404, manufactured by Grace, Davidson Chemical, Baltimore, Maryland, U.S.A.); 20 gms of Raven 7000 channel black, manufactured by Cities Services Company and 1.3 gms of the slip used in Example 1.

25 This formulation was then placed in a one-quart ceramic ball jar along with various sized ceramic balls and ball-milled for about 16 hours on a roller. This treatment resulted in a black pigmented coating resin. This material was designated as 12A. A second material, prepared from

-18-

the resin composition as used in sample 12A (230.8 gms) was treated with 90 gms of R-900 TiO₂, manufactured by DuPont, Wilmington, Delaware, U.S.A. and 159.2 gms of toluene.

This material was also ball milled for 16 hours
5 to give a white coating. This material was designated 12B. When these materials were coated on aluminum panels, the following results were achieved. (See Table X).

Claims:

1. A composition of matter comprising

- (A) 100 parts by weight of a hydroxyfunctional polysiloxane resin copolymer containing $\text{CH}_3\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units, $(\text{C}_6\text{H}_5)_2\text{SiO}$ units and $\text{C}_6\text{H}_5(\text{CH}_3)\text{SiO}$ units wherein there is present 0.5 to 5 weight percent hydroxy radicals attached to silicon atoms, the organic group to silicon ratio is from 0.8 to 1.4 and the C_6H_5^- to silicon ratio is from 0.35 to 0.85;
- (B) from 4 to 240 parts by weight, based on 100 parts of (A), of $\text{CH}_3\text{SiO}_{3/2}$;
- (C) from 0.2 to 6 parts by weight, based on 100 parts of (A), of a fluid polysiloxane having the formula $(\text{RR}'\text{R}''\text{Si})_2\text{O}[(\text{CH}_3)_2\text{SiO}]_x$, wherein x has a value of from 250 to 850, R is OH or CH_3^- and R' and R'' are CH_3^- , wherein there is present in component (C), less than fifteen percent by weight of $(\text{CH}_3)_3\text{SiO}$ units; and
- (D) from 0.48 to 6 parts by weight, based on 100 parts of (A), of a curing agent.

2. A composition as claimed in claim 1 wherein component (D) is a titanium ester.

3. A composition as claimed in claim 1 wherein there is also a solvent present.

4. A composition as claimed in claim 1 wherein there is also present a mixture of solvents.

5. An article comprising a solid substrate coated with a composition of matter comprising

- (A) 100 parts by weight of a hydroxyfunctional polysiloxane resin copolymer containing $\text{CH}_3\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units, $(\text{C}_6\text{H}_5)_2\text{SiO}$ units and $\text{C}_6\text{H}_5(\text{CH}_3)\text{SiO}$ units wherein there is present 0.5 to 5 weight percent hydroxy radicals attached to silicon atoms, the organic group to silicon ratio is from 0.8 to 1.4 and the C_6H_5 - to silicon ratio is from 0.35 to 0.85;
- (B) from 4 to 240 parts by weight, based on 100 parts of (A), of $\text{CH}_3\text{SiO}_{3/2}$;
- (C) from 0.2 to 6 parts by weight, based on 100 parts of (A), of a fluid polysiloxane having the formula $(\text{RR}'\text{R}''\text{Si})_2\text{O}[(\text{CH}_3)_2\text{SiO}]_x$, wherein x has a value of from 250 to 850, R is OH or CH_3^- and R' and R'' are CH_3^- , wherein there is present in component (C), less than fifteen percent by weight of $(\text{CH}_3)_3\text{SiO}$ units; and
- (D) from 0.48 to 6 parts by weight, based on 100 parts of (A), of a curing agent.

6. A method of enhancing release from the surface of a solid substrate which method comprises

- (i) coating a solid substrate with a composition of matter comprising
 - (A) 100 parts by weight of a hydroxyfunctional polysiloxane resin copolymer containing $\text{CH}_3\text{SiO}_{3/2}$ units, $\text{C}_6\text{H}_5\text{SiO}_{3/2}$ units,

$(C_6H_5)_2SiO$ units and $C_6H_5(CH_3)SiO$ units wherein there is present 0.5 to 5 weight percent hydroxy radicals attached to silicon atoms, the organic group to silicon ratio is from 0.8 to 1.4 and the C_6H_5 - to silicon ratio is from 0.35 to 0.85;

- (B) from 4 to 240 parts by weight, based on 100 parts of (A), of $CH_3SiO_{3/2}$;
- (C) from 0.2 to 6 parts by weight, based on 100 parts of (A), of a fluid polysiloxane having the formula $(RR'R''Si)_2O[(CH_3)_2SiO]_x$, wherein x has a value of from 250 to 850, R is OH or CH_3 - and R' and R'' are CH_3 -, wherein there is present in component (C), less than fifteen percent by weight of $(CH_3)_3SiO$ units; and
- (D) from 0.48 to 6 parts by weight, based on 100 parts of (A), of a curing agent and,
 - (ii) curing the coating, whereupon a solid substrate, having enhanced release, is obtained.
